

# Combining GLM and ABI Data for Enhanced GOES-R Rainfall Estimates

Robert Adler, Weixin Xu  
and Nai-Yu Wang  
*CICS/University of Maryland*

A combination of existing project under Wang dealing with microwave/lightning relations and new proposal by Adler on IR/lightning rain estimation, both focused on improving GOES-R Baseline rain algorithm (Kuligowski).

[2 journal papers recently submitted](#)

Xu, W., R. F. Adler, and N.-Y. Wang, 2012: Improving Geostationary Satellite Rainfall Estimates Using Lightning Observations, I: Underlying Lightning-Rainfall Relationships. *J. Appl. Meteor. Climatol.*, (submitted).

Wang, N-Y, K. Gopalan, and R. Albrecht, 2012: Lightning, radar reflectivity and passive microwave observations over land from TRMM: Characteristics and application in rainfall retrievals, *J. Geophysical Research* (submitted).

# Issues and Motivation

## Limitations of infrared-based rain estimates:

- Only “see” the top of precipitating cloud;  
(though cloud growth or structure can be considered)
- May treat cold cirrus clouds as intense convection;
- May misrepresent convective rain: location, area and rain intensity;  
(especially under relatively uniform cold cloud shields in mature MCSs)

*(but geostationary rain estimation still very important because of temporal resolution and rapid access)*

## **How would lightning information help?**

- Provide information associated with convection location and intensity (~ rainfall rate)

# Objectives

Design a lightning-enhanced geostationary IR technique to

Remove false IR-defined intense convection

Identify convective cores and conv. rain area below cloud shields

Define correct rain intensity (on pixel scale)

Improve microwave-based calibration of IR technique

## Recent Work/Approach

Examine lightning-cloud-rain relations with TRMM observations (papers submitted)

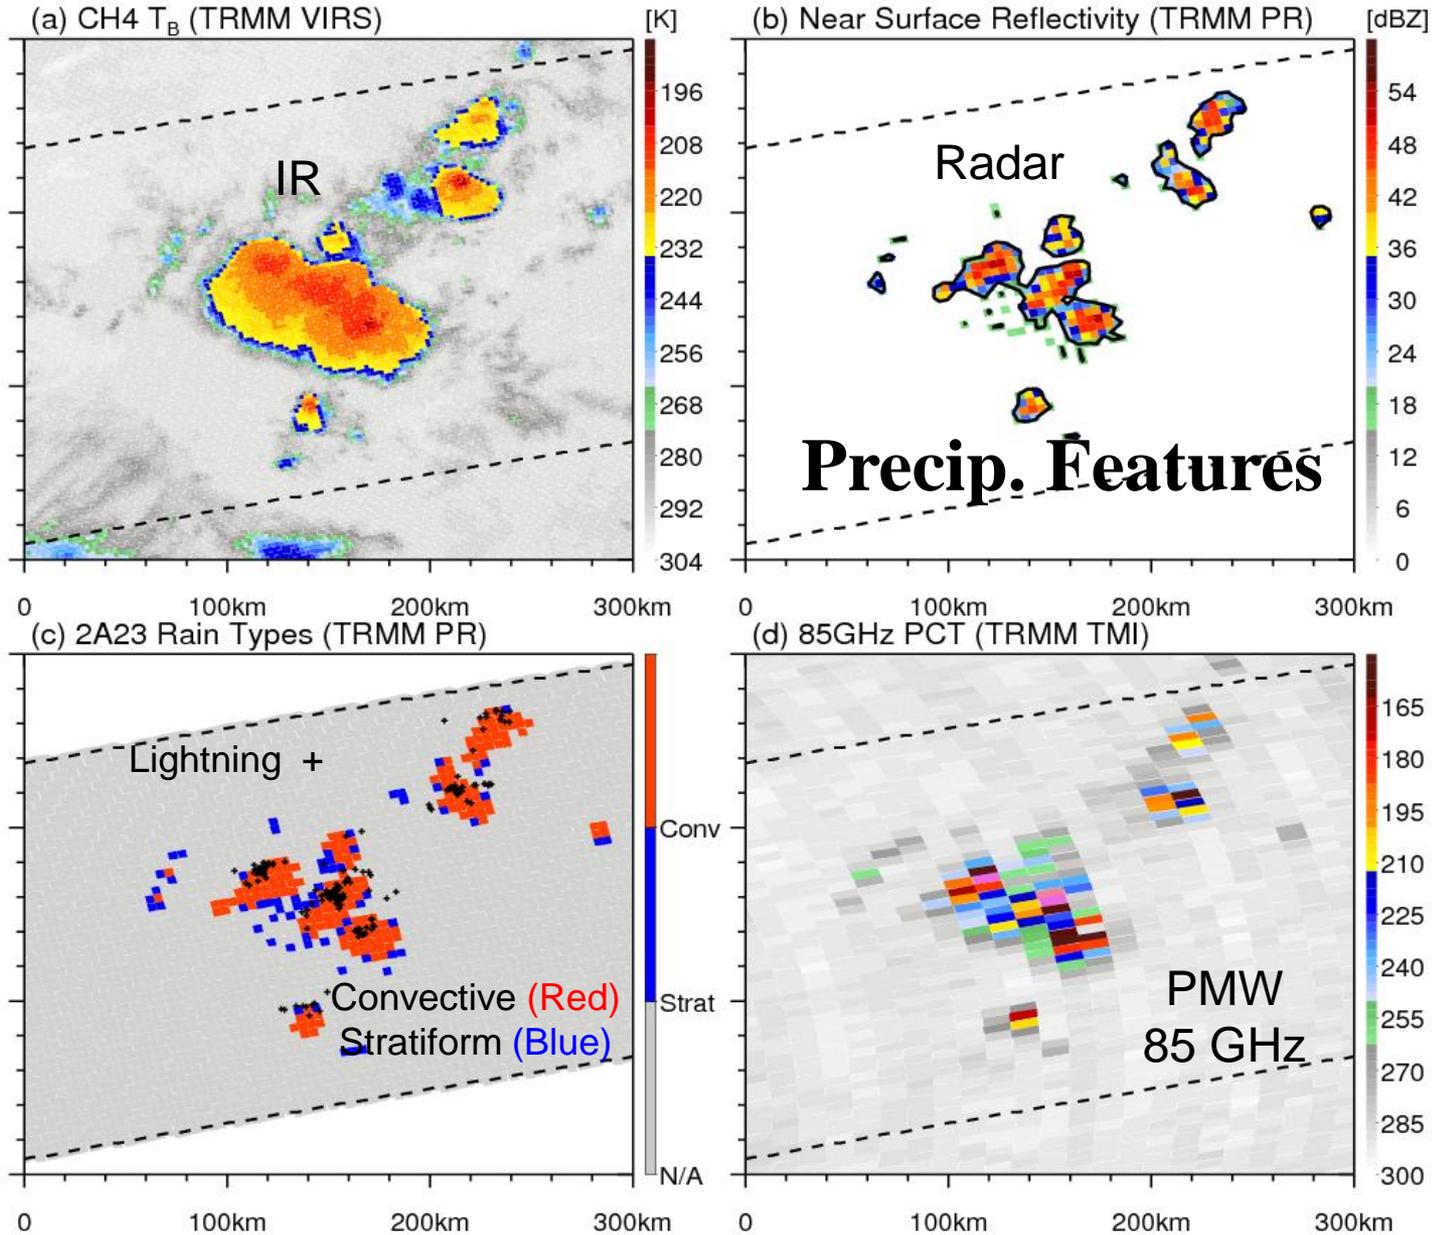

Develop a rain estimation technique to take advantage of lightning information potential—apply to TRMM data

Compare to Baseline algorithm

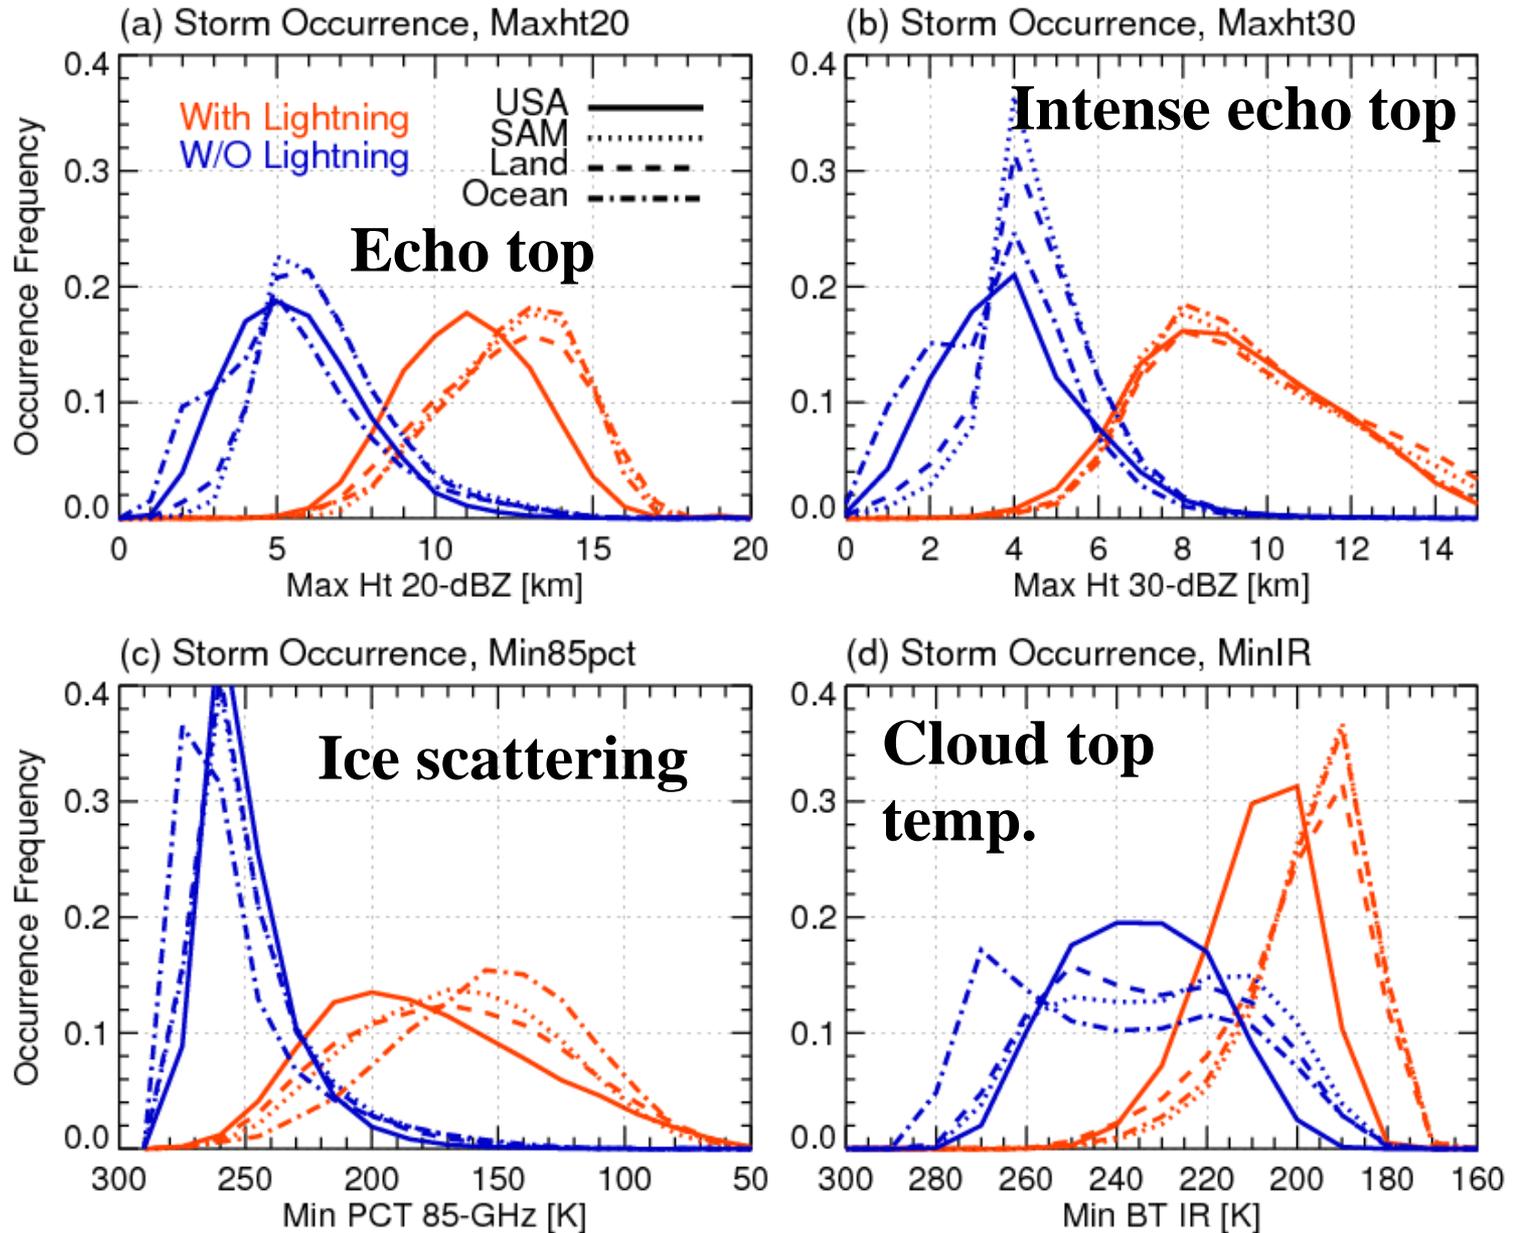

# **Relationships between Lightning and Convective Rainfall**

# Precipitation Features (radar raining clusters)

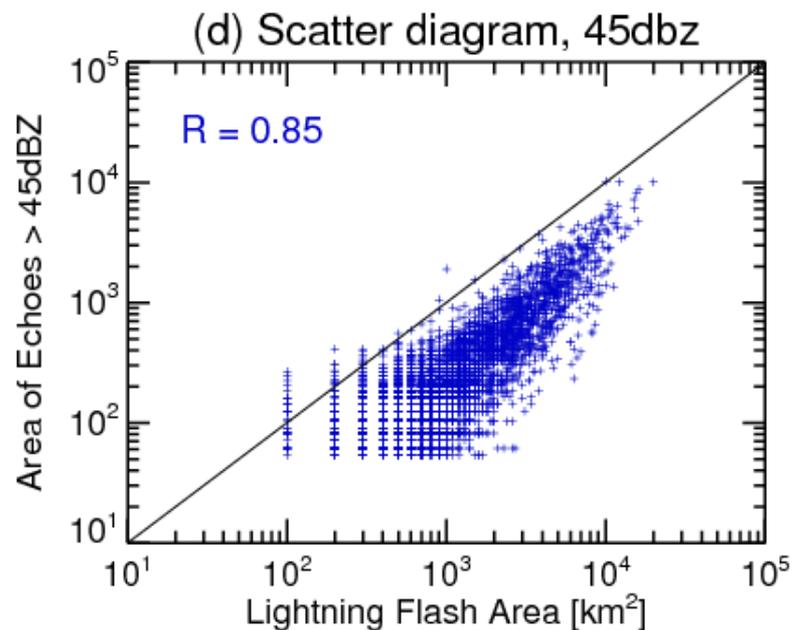

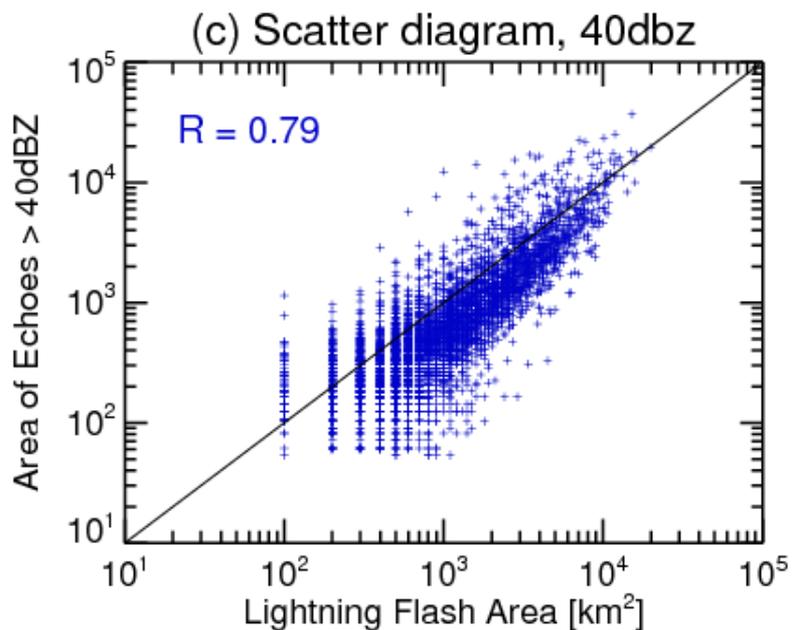

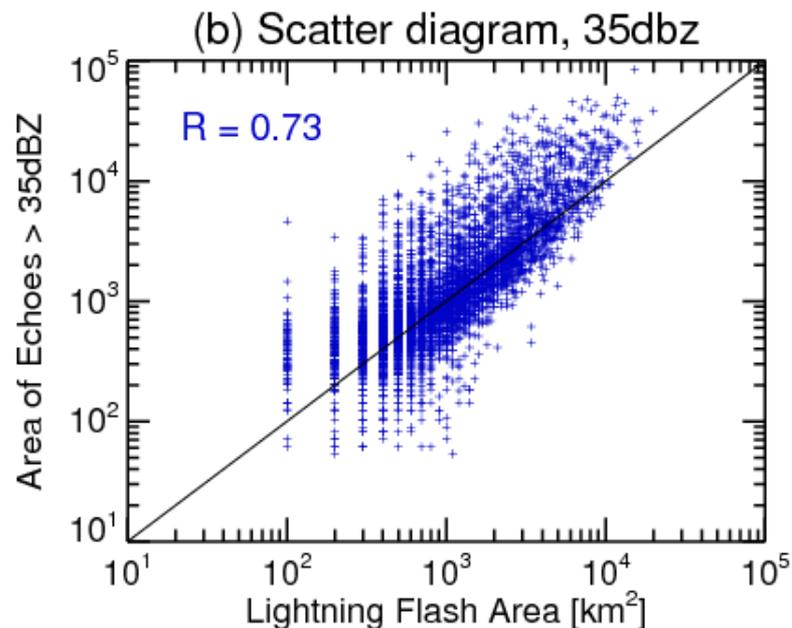

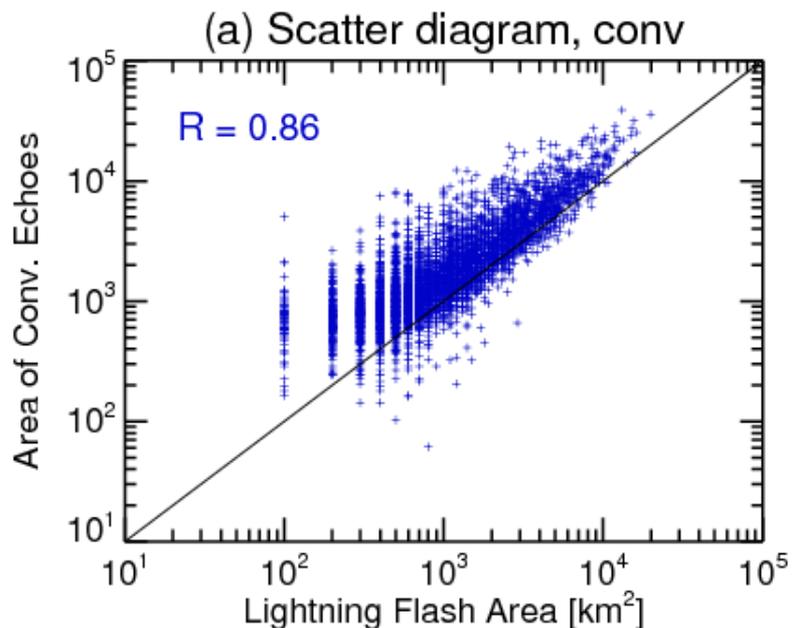

*From University of Utah TRMM Precipitation Feature (PF) Database*

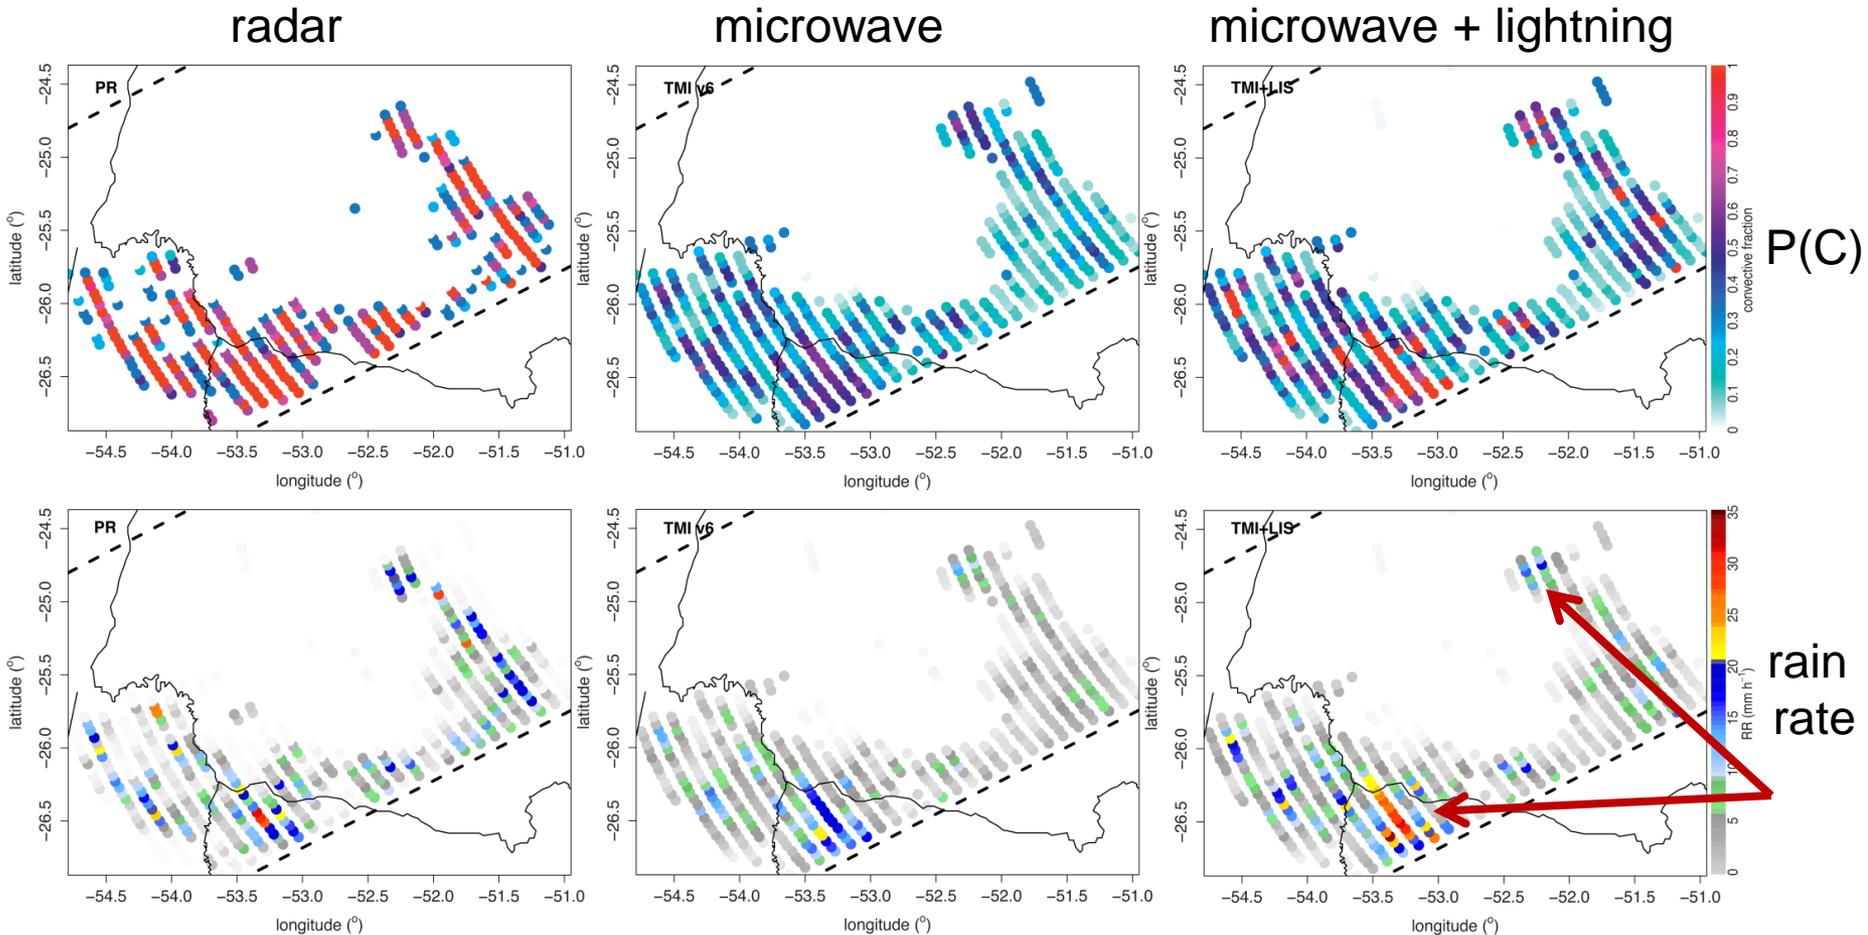

# Storm discrimination by lightning

# Defining Conv. Area (by lightning flash area)

# Improvement of Passive Microwave Retrievals (Used as Calibrator for IR Baseline Algorithm) An Example: Lightning Impact on Rain Rate Retrievals

Overall impact of lightning on rain rate is 5-10%, but focused on highest rain rates

# IR (and IR + Lightning) Rain Estimation Applied to TRMM Data

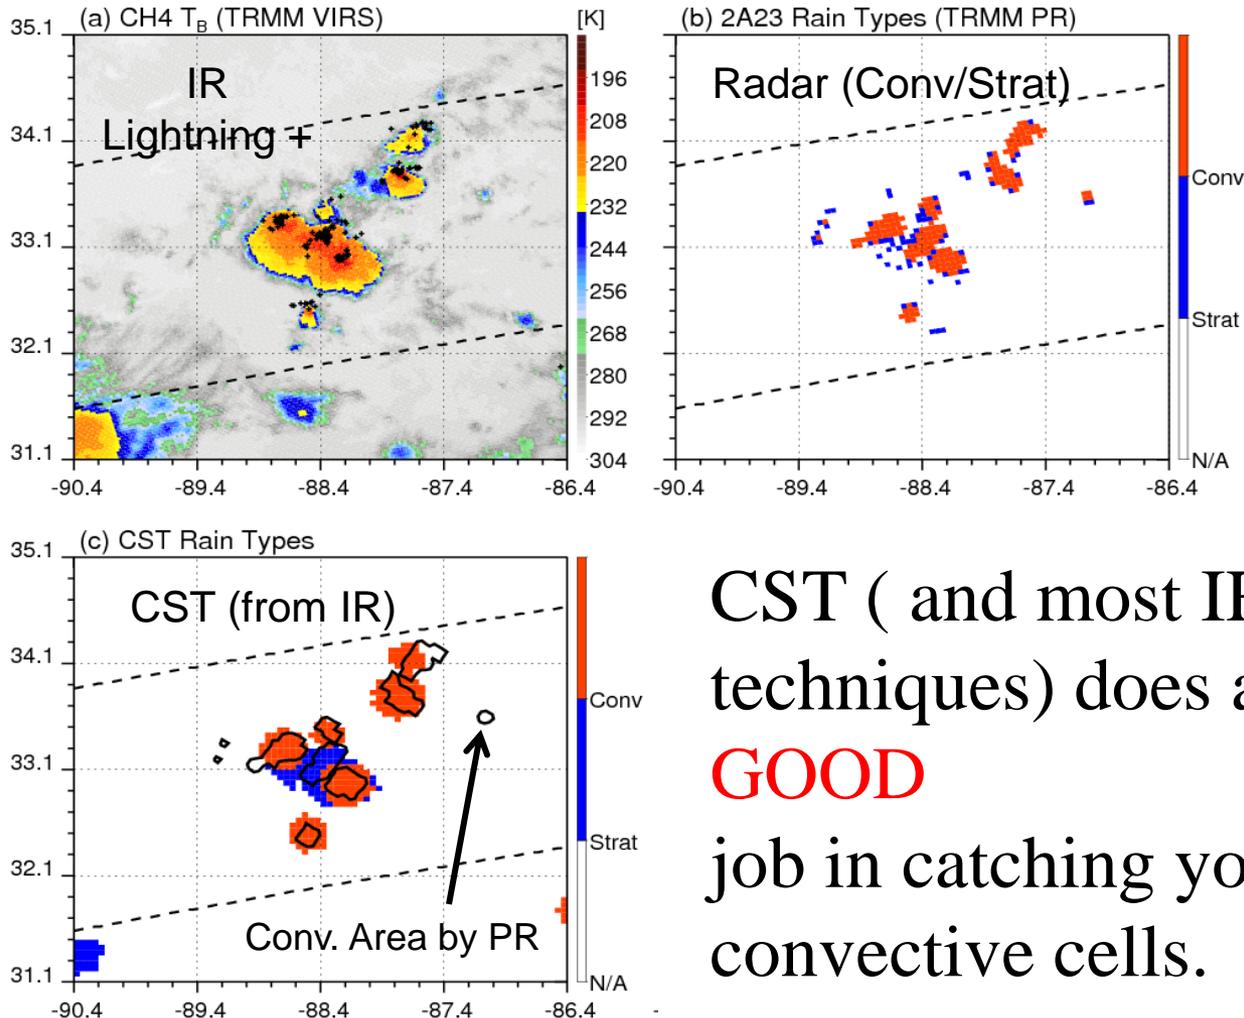

- Initial IR technique is variation of Convective Stratiform Technique (CST, Adler and Negri, 1988)
- Defines convective core/areas by IR  $T_b$  minima (with some tests) and stratiform rain area by  $T_b$  threshold (usually cold  $\sim 215K$ ). Rain rates in convective and stratiform areas derived separately and empirically
- Lightning information will be used to define convective cores “unseen” by IR and eliminate IR cloud top minima incorrectly identified as “convective”

# IR-based C/S Technique (CST)

STEPS: (Adler and Negri, 1988)

1. Local Tb minima;
2. Slope test;

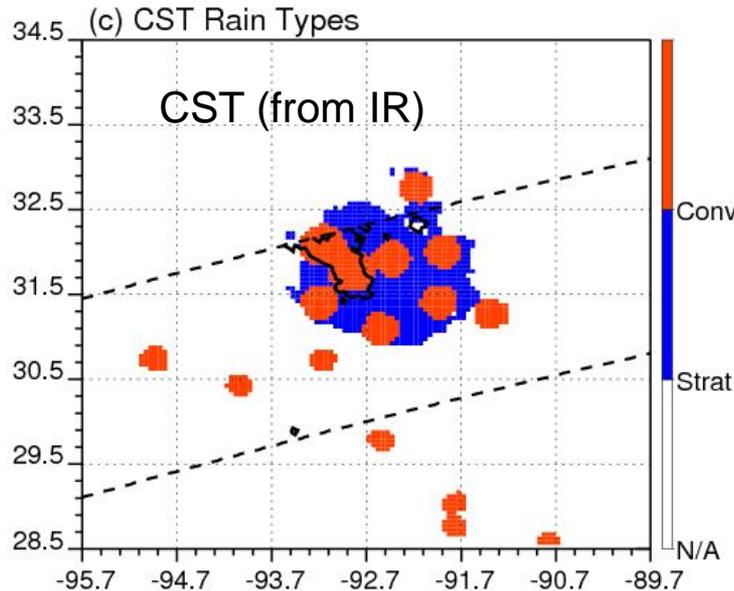

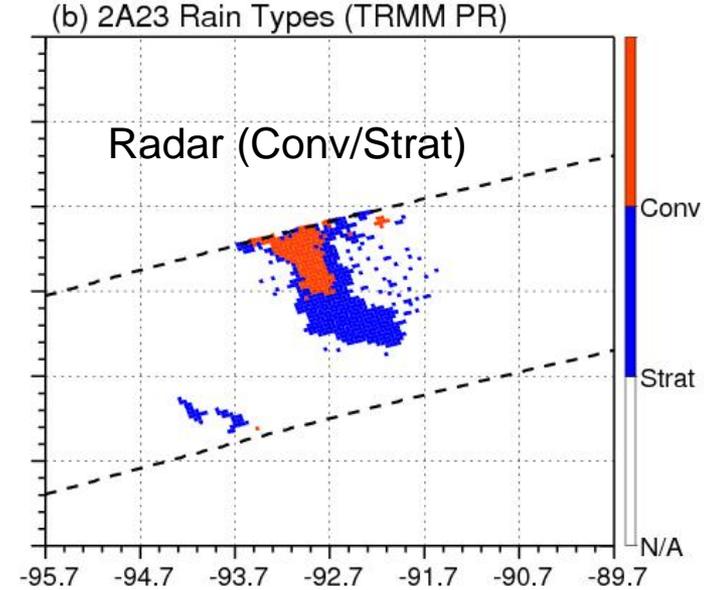

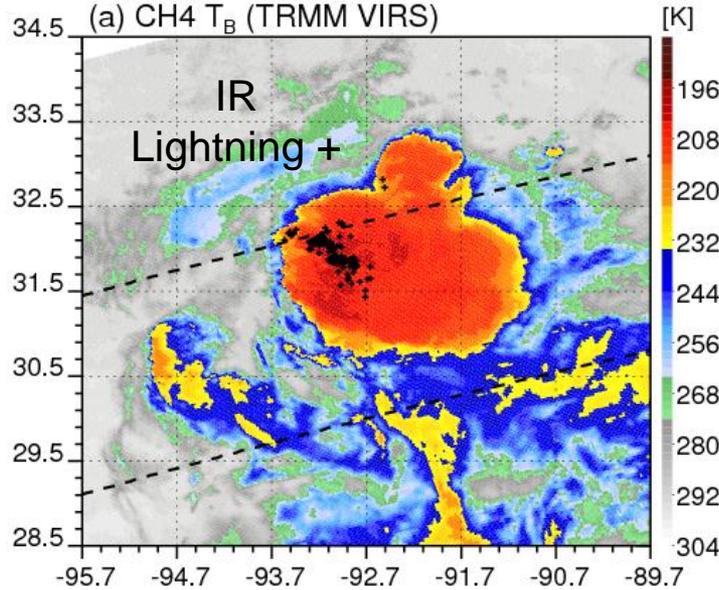

20060719, 0224UTC, Orbit: 49426, Lat: 33.1, Lon: -88.4

CST ( and most IR techniques) does a **GOOD** job in catching young convective cells.

# IR-based C/S Technique (CST)

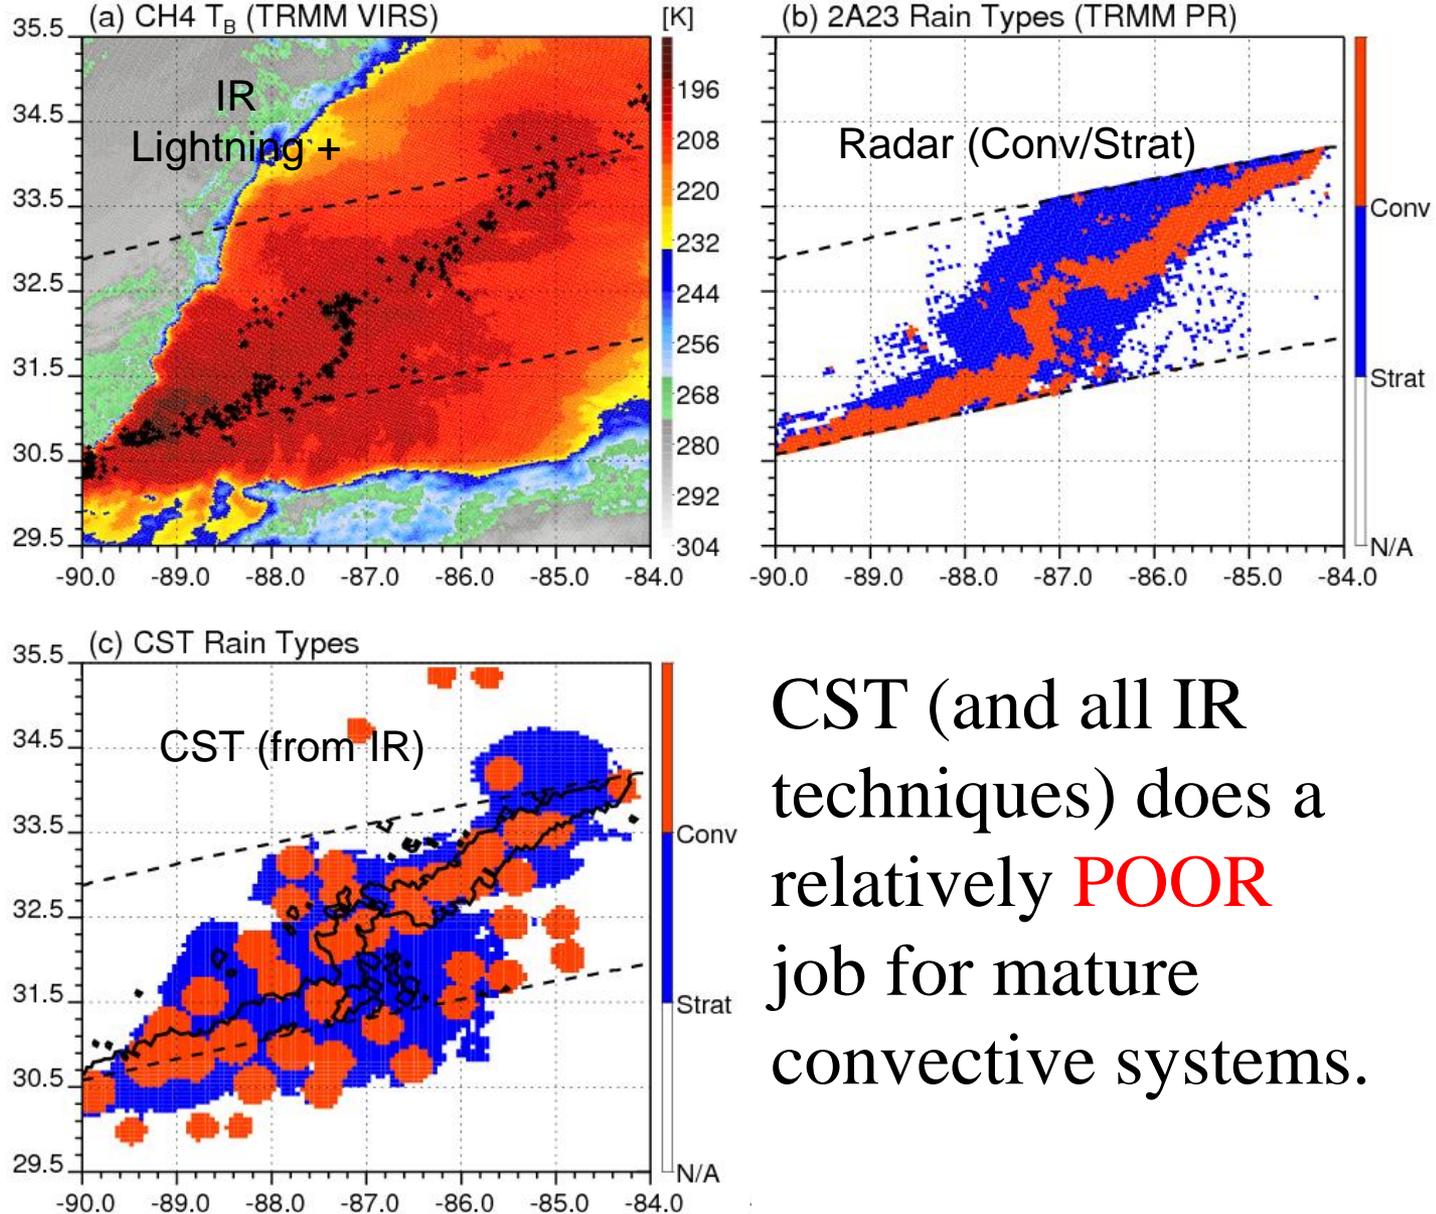

20030718, 0551UTC, Orbit: 32330, Lat: 31.5, Lon: -92.7

CST becomes **VAGUE**  
as convective systems  
develop (too many  
convective cores)

# IR-based C/S Technique (CST)

20050430, 1121UTC, Orbit: 42496, Lat: 32.5, Lon: -87.0

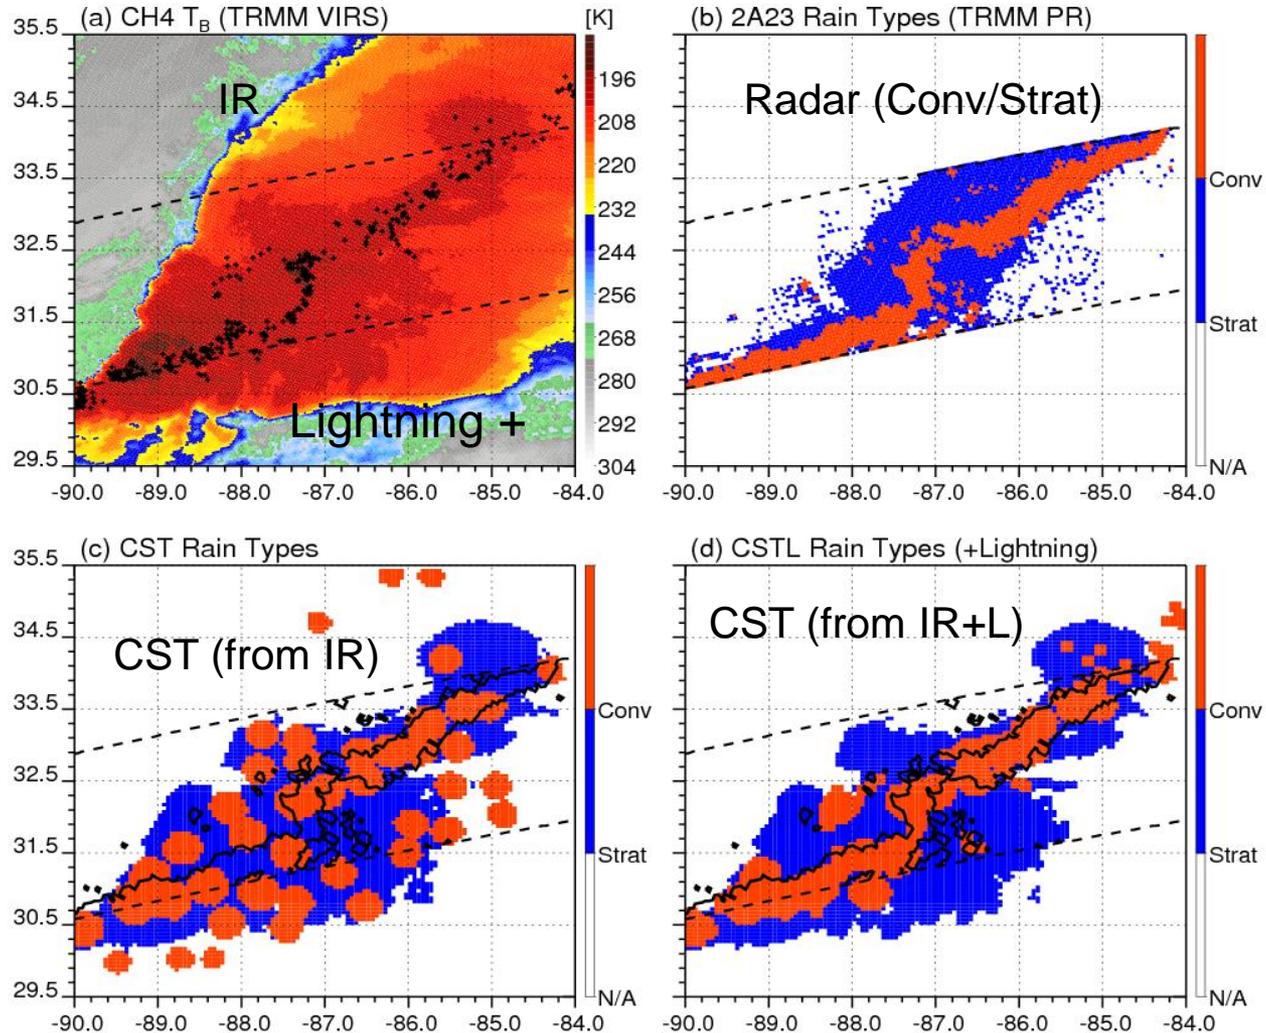

CST (and all IR techniques) does a relatively **POOR** job for mature convective systems.

# IR-Lighting-Combined C/S Technique (CSTL)

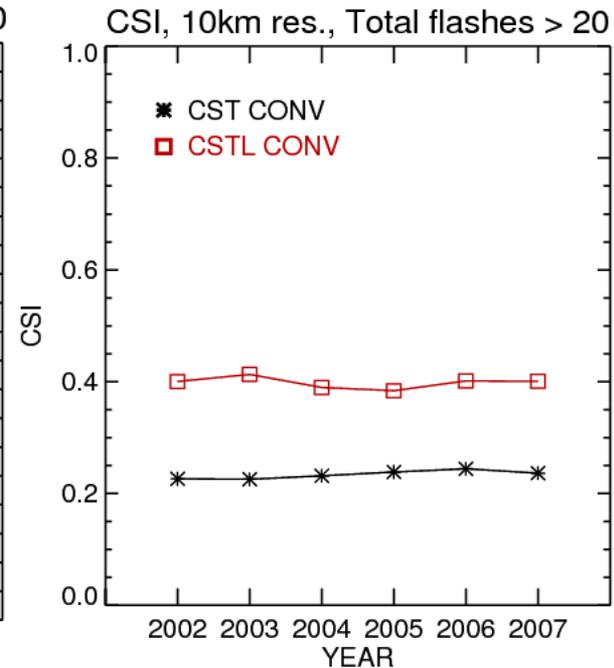

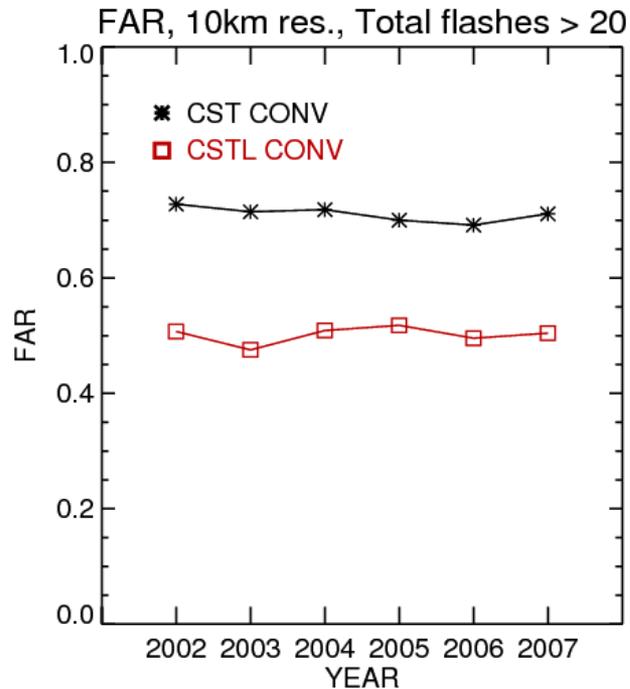

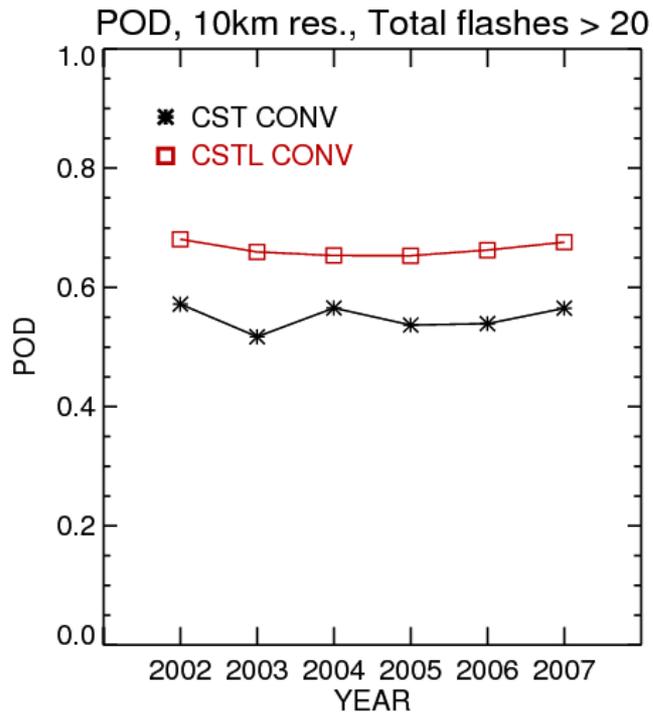

1. Conv. cores w/o lightning in mature systems are removed
2. Conv. areas (with flash) missed by CST are added;

20050430, 1121UTC, Orbit: 42496, Lat: 32.5, Lon: -87.0

# Identification of Convective Cores by Adding Lightning

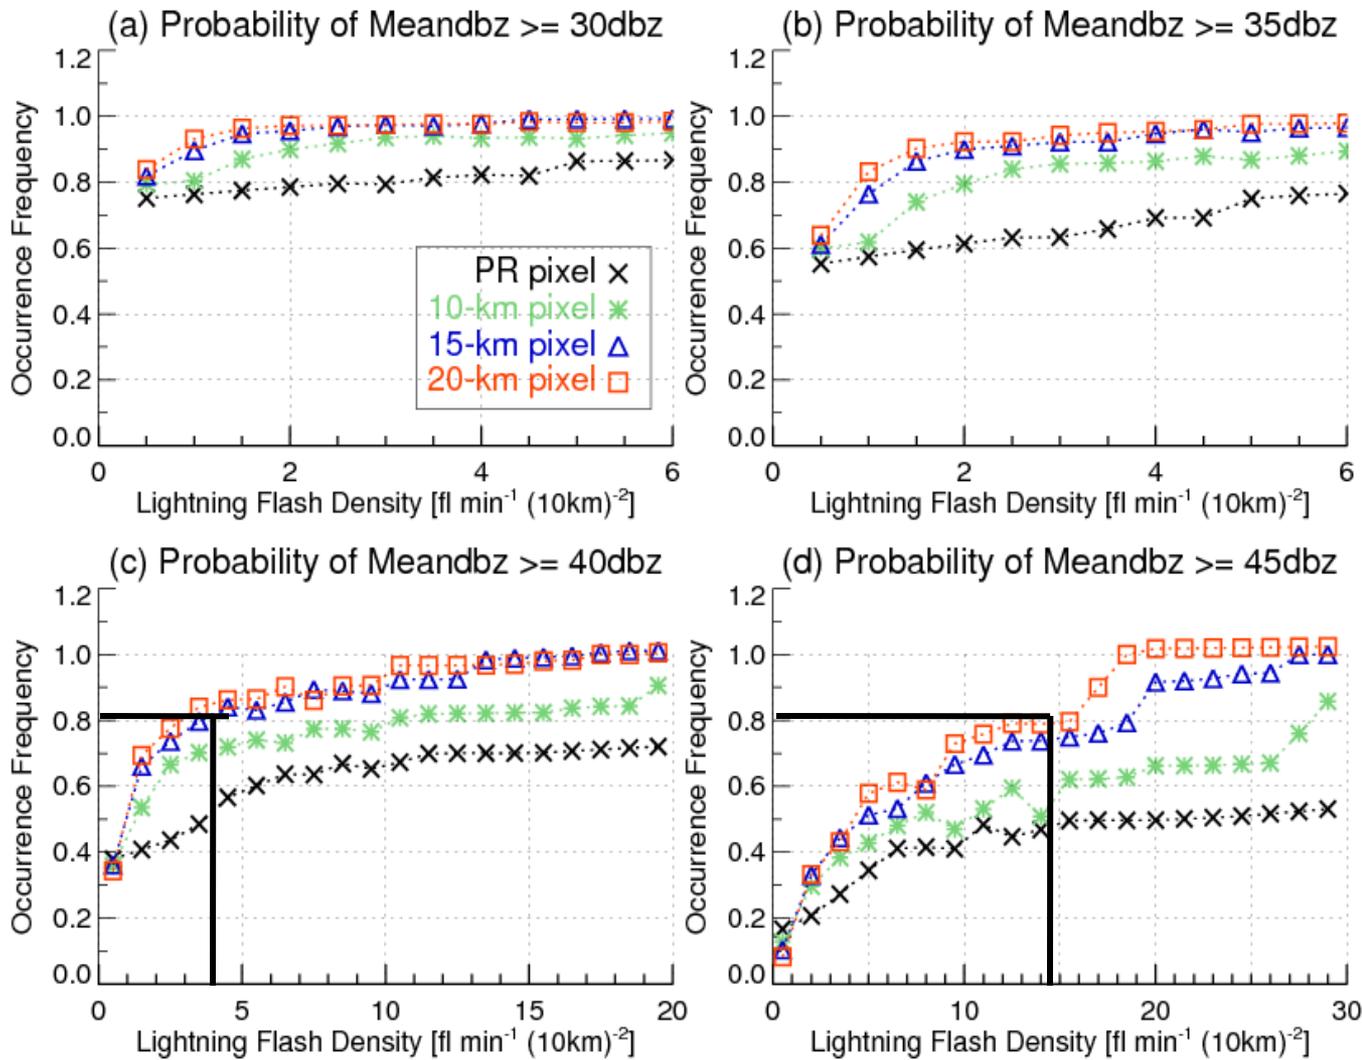

- \* Estimates of Convective ID evaluated by PR;
- \* CST and CSTL run in an area (600x600 km<sup>2</sup>);
- \* 2000 cases (> 20 lightning flashes) are selected;

1. Lightning improves the convective detection (POD)
2. Lightning lowers the false alarm (FAR)

# **“Full” Version of CSTL with Rainfall Rate**

# Flash Rate Density/ Rain Rate Relationships

Used to guide assignment of rain rate based on flash density (fl/min/100km<sup>2</sup>)

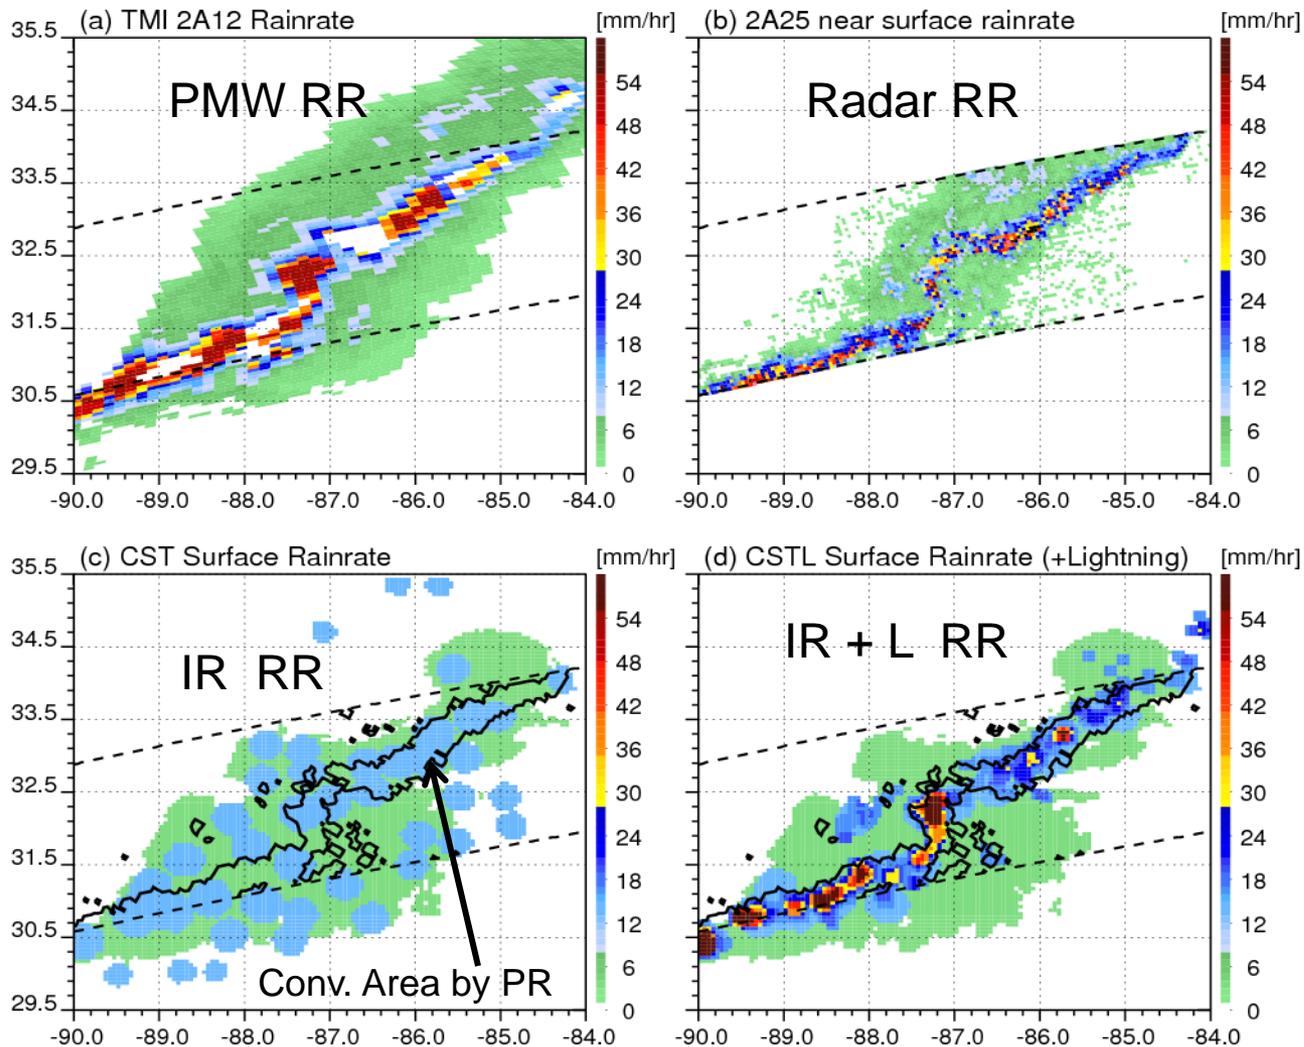

At 20 km resolution:

FD	dBZ	RR(mm/h)
4	40	15
15	45	22
35	55	45

# Assigning Rainfall Rate

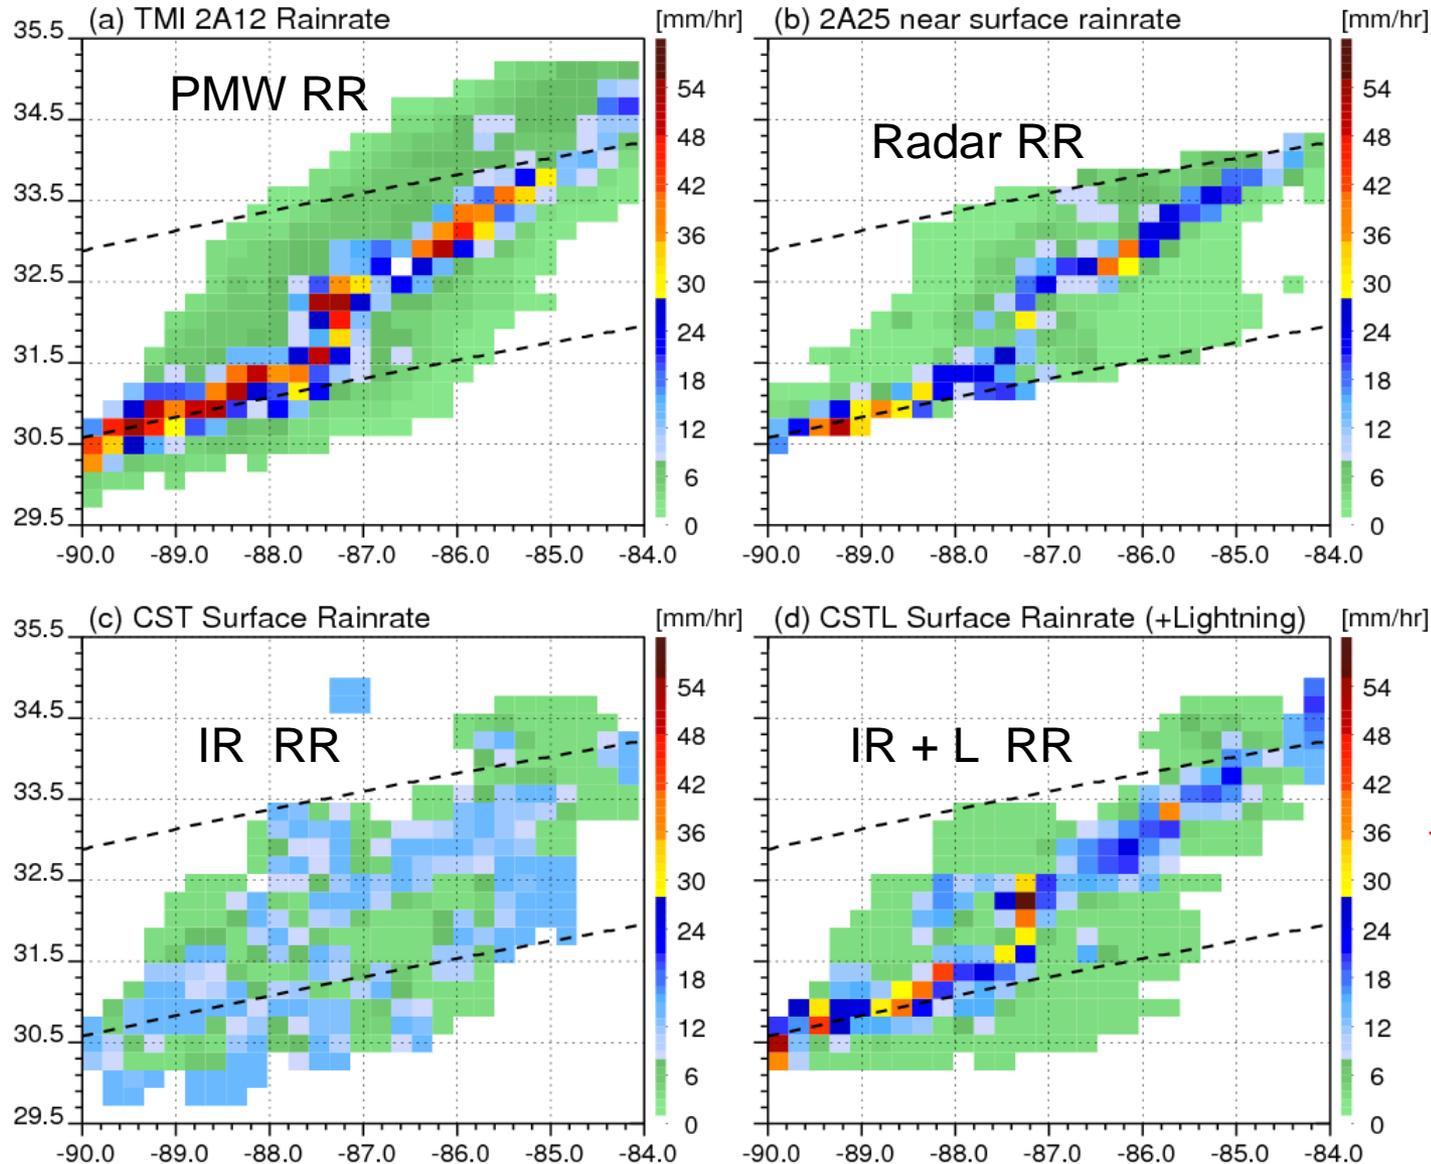

1. Stratiform: 2.5 mm/hr; 2: Convective:12.5 mm/hr;
2. CSTL is assigned discretely with flashes in 20 km;

20050430, 1121UTC, Orbit: 42496, Lat: 32.5, Lon: -87.0

# Assigning Rainfall Rate (20 km resolution)

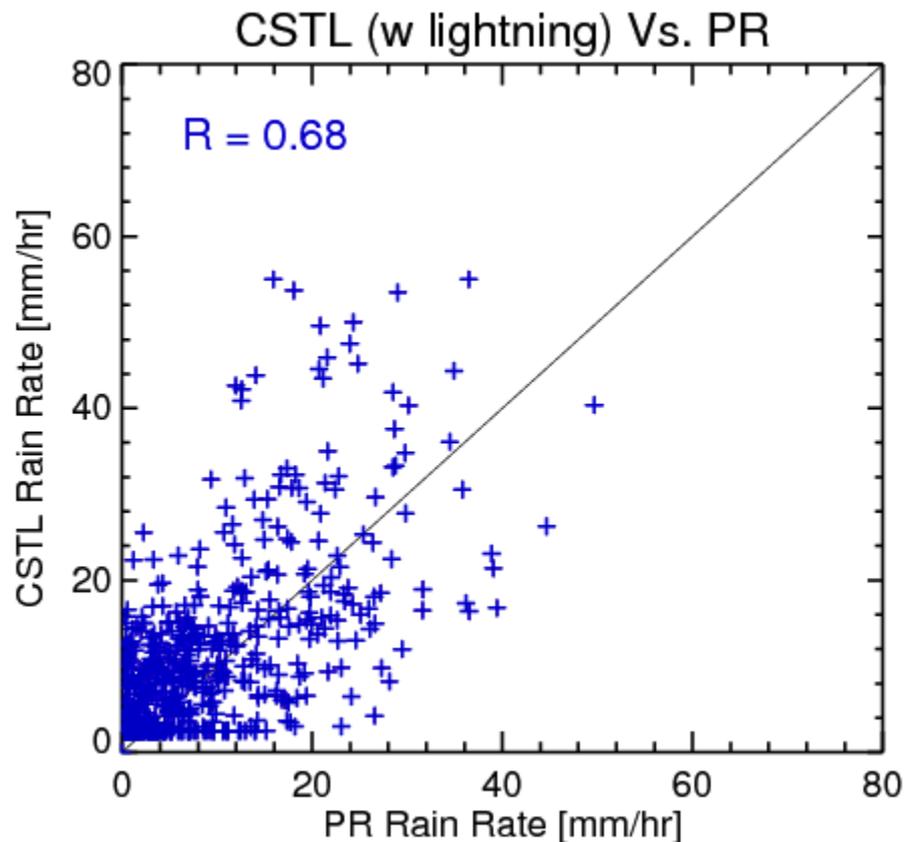

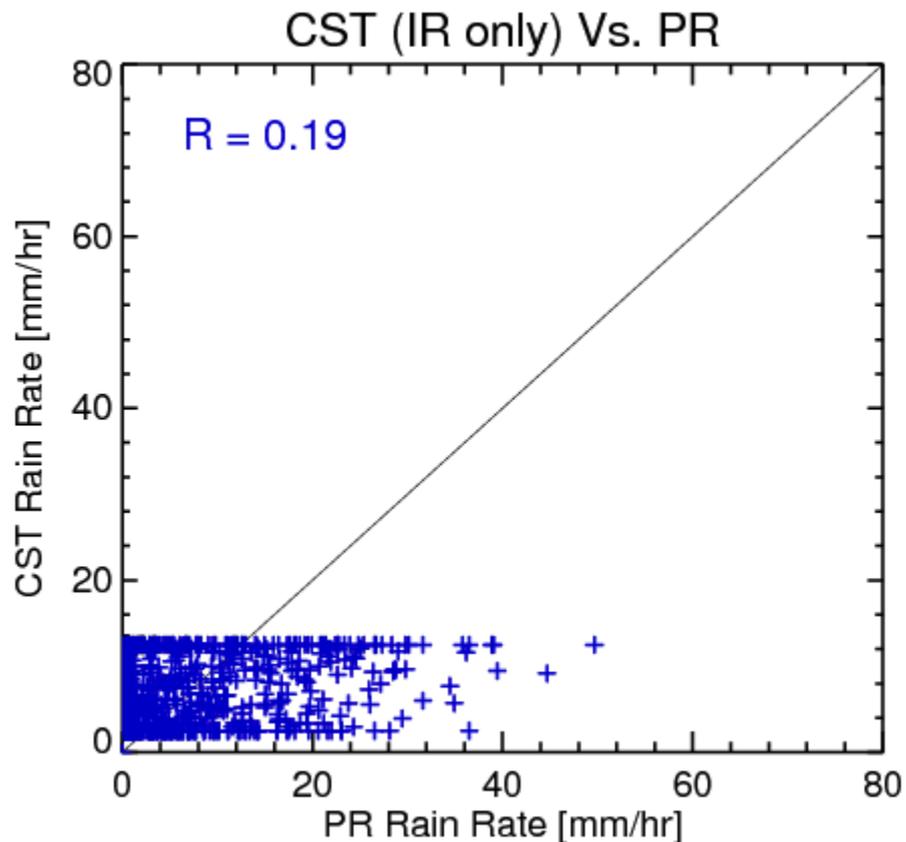

20050430, 1121UTC, Orbit: 42496, Lat: 32.5, Lon: -87.0

Vs. PR

Vs. TMI

# Summary/Next Steps

- Lightning/cloud/rain relations have been established for use in developing GLM/ABI combined rain estimation (papers submitted)
- Initial work completed in developing framework for testing IR (and IR + lightning) rain estimation with TRMM data and for comparing results with GOES-R baseline algorithm
- Preliminary results indicate obvious value of lightning information to establish location of convective cores “unseen” by IR and eliminate incorrect core identification by IR. **Preliminary statistics indicate significant improvement** in rain estimation with use of lightning data
- Next steps include:
  - full analysis of TRMM IR and IR+L rain estimation to carefully quantify lightning impact and its potential and limitations in comparison/ combination with Baseline algorithm
  - use of CHUVA and other data sets to evaluate IR+L with Baseline and test with time resolution/evolution
  - continue analysis of lightning impact on microwave rain retrievals using TRMM data
